Meridian Platform Q3 2026 Release Notes — v2.4

Document ID: MGC-REL-2026-Q3-2.4

Date: September 15, 2026

Product: Meridian Platform (Data & Analytics)

Version: 2.4.0

Target Audience: All Meridian Platform tenants, administrators, and developers

Overview

Meridian Global Corp is pleased to announce the general availability of Platform v2.4. This release delivers significant enhancements to data querying, security governance, and export capabilities, alongside a major performance uplift and critical stability fixes. A total of 47 bugs have been resolved, including a high-severity issue affecting query timeout behavior on very large datasets. All tenants are encouraged to upgrade before October 15, 2026, to ensure continued support and access to the latest features.

New in v2.4

AI Query Suggestions (Powered by Fine-Tuned LLM)

The Meridian Query Editor now offers intelligent, context-aware suggestions for SQL and GraphQL queries. The underlying large language model has been fine-tuned on anonymized platform query logs and public dataset schemas. Suggestions appear as you type, covering common aggregations, filter patterns, and join optimizations. To enable, toggle “AI Suggestions” in the workspace settings. Initial internal tests show a 30% reduction in time-to-first-query for new users. This feature is available on all plans except the Starter tier.

Bulk CSV Export (Up to 10 Million Rows)

Users can now export query results directly to CSV with a single API call or UI action, supporting up to 10 million rows per export. The export engine uses streaming

compression and parallel chunking to minimize memory overhead. Exports are delivered via signed download URL (expires after 24 hours) or written to a configurable cloud storage bucket. This feature replaces the prior row limit of 500,000 and is ideal for data integration workflows.

****RBAC Enhancements: Row-Level Security & Column Masking****

Two new access control capabilities are introduced for governed data workspaces:

- ****Row-Level Security (RLS):**** Administrators can define filter predicates per role (e.g., `region = 'EMEA'` for the Sales Analyst role). Policies are enforced at query execution time, independent of the query itself. Maximum of 100 policies per workspace.
- ****Column Masking:**** Sensitive columns (e.g., `email`, `salary`) can be masked under any condition (e.g., show first three characters only, or full redaction). Masking is role-dependent and applies to all export and visualization outputs.

Both features require the “Governance Admin” role within a workspace. Documentation for policy syntax is available in the Meridian Admin Guide (v2.4).

Bug Fixes

A complete list of the 47 resolved issues is accessible in the Meridian Support Portal (ticket group #REL-2.4-FIX). Key highlights include:

- ****Critical Fix – Query Timeout on Datasets >500 GB**** (TICKET-2026-08942): Queries scanning datasets larger than 500 GB would intermittently time out after 120 seconds, even with adequate execution resources. The root cause — a suboptimal memory reclamation loop in the distributed execution engine — has been patched. Queries now respect the configured timeout (default 600 seconds) regardless of dataset size.
- ****CVE-2026-0137 – API Token Exposure in Audit Logs:**** Fixed a logging issue where API tokens could appear in debug-level audit logs under high concurrency. All tenants are advised to rotate any tokens used between August 1 and September 12, 2026.
- ****GraphQL Mutation Ordering (TICKET-2026-09101):**** Resolved an incorrect response order for batch mutations when using default pagination.

Performance Improvements

****40% Faster Query Response via Query Plan Caching****

The platform now caches compiled query plans (including access paths, join orders, and filter pushdown decisions) for up to 24 hours, keyed by query fingerprint. For repeated queries — common in dashboards and scheduled reports — this eliminates the planning overhead, resulting in a median 40% reduction in response latency. The cache is automatically invalidated when underlying schemas or row-level security policies change. No configuration changes are required.

Breaking Changes

****Deprecation of /v1/legacy Endpoint****

As announced in v2.3 release notes (June 2026), the `/v1/legacy`` REST endpoint is formally retired. As of **\*\*September 1, 2026\*\***, all requests to `/v1/legacy`` return HTTP ****410 Gone****. The replacement `/v2`` endpoints (available since v2.0) are fully backwards-compatible for data operations; authentication and pagination parameters remain unchanged. Customers still using `/v1/legacy`` must migrate to `/v2`` immediately. The Meridian Migration Toolkit (`meridian-migrate``) can assist with automated conversion of scripts and SDK calls.

Known Issues

****GraphQL Subscriptions May Drop on Network Interruption****

We have identified an issue where GraphQL subscription connections may not properly recover after a transient network interruption (e.g., brief client-side disconnection). The subscription silently closes, and no error is surfaced to the client. A fix is planned for the upcoming v2.4.1 patch release, expected by October 5, 2026. As a workaround, clients are advised to implement reconnection logic using the recommended `@meridian/subscriptions`` library (version $\geq 1.3.0$), which includes an automatic retry mechanism.
